

Artificial intelligence is a broad concept that aims to enable machines to think and perform tasks similar to humans. Machine learning is a major approach to achieve artificial intelligence. It focuses on learning patterns from data.

Deep learning is a branch of machine learning based on neural networks that can automatically learn feature representations from data.

→ Neural networks are computer systems inspired by the human brain that learn to recognize patterns and solve complex problems.

14. Natural language Processing (NLP) is a branch of artificial intelligence and computer science that helps computers understand, interpret and generate human language. It bridges the gap between human communication and machine understanding by combining linguistics, computer science and machine learning.
