

Raw text is broken down into smaller pieces on figuring out the meaning behind words or audio. Natural language understanding figures out the meaning behind the audio or words. Natural language generation allows the computer to write or speak a helpful human like response.

Examples: Voice assistants, Chatbots and Machine Translation

15. A large language model (LLM) is an artificial intelligence system trained on massive amounts of text to understand, summarize, translate and generate human like language. Primary difference is that Machine Learning is a broad field of AI where computers learn patterns from data, while an LLM is a specific type of deep learning model built to process text and conversation.

Examples: GPT-4o (OpenAI) A powerful proprietary model used in ChatGPT that handles advanced dialogue, coding and reasoning. Gemini (Google) A multimodal model family built to understand text, images, audio, and video across Google products.

16. Generative AI is a type of artificial intelligence that is (specific deep learning) it learns the underlying patterns of a massive dataset to produce original human-like outputs. It operates on Training & Inference @ Training (Learning the Patterns)

The AI views billions of examples, such as books, websites. Using computer systems inspired by the human brain it maps out how words, sounds, or pixels relate to another. It then builds a massive mathematical map of probabilities.
