

It provides summarised data that key stakeholders can use to quickly make informed decisions.

Data mart vs data warehouse

Data mart shares many of the qualities of data warehouse, where they differ is that a data warehouse contains enterprise-wide data about various topics. While a data mart stores information closely related to a specific subject. Example, a data warehouse might store information for the marketing, human resource and customer departments. However, a data mart might store only transactional data relevant to a single department. Organizations use data marts so that departments who manage their data marts have complete control over the loading and management of their data.

5. Structured data

→ It is organised in a clear, predefined format. It can include both quantitative data (such as prices or revenue fig) and qualitative data (dates, names & addresses) eg. A Financial report with company names. Typically stored in tabular formats, such as Excel spreadsheets and relational databases. Structured data has an abundance of tools for use and data analysis. eg Online Analytical processing, MySQL & PostgreSQL. But it is has limited usage as it can be used for its intended purposes which limits flexibility and usability.

Unstructured data

It does not have a predefined format. They are large data sets, complex datasets from the internet and other connected technologies. They support big data.
